List Index

Tobias Nipkow

February 6, 2026

Abstract

This theory provides functions for finding the index of an element in a list, by predicate and by value.

1 Index-based manipulation of lists

theory *List-Index* **imports** *Main* **begin**

This theory collects functions for index-based manipulation of lists.

1.1 Finding an index

This subsection defines three functions for finding the index of items in a list:

find-index P xs finds the index of the first element in *xs* that satisfies *P*.

index xs x finds the index of the first occurrence of *x* in *xs*.

last-index xs x finds the index of the last occurrence of *x* in *xs*.

All functions return *length xs* if *xs* does not contain a suitable element.

The argument order of *find-index* follows the function of the same name in the Haskell standard library. For *index* (and *last-index*) the order is intentionally reversed: *index* maps lists to a mapping from elements to their indices, almost the inverse of function *nth*.

```
primrec find-index :: ('a ⇒ bool) ⇒ 'a list ⇒ nat where
  find-index - [] = 0 |
  find-index P (x#xs) = (if P x then 0 else find-index P xs + 1)

definition index :: 'a list ⇒ 'a ⇒ nat where
  index xs = (λa. find-index (λx. x=a) xs)

definition last-index :: 'a list ⇒ 'a ⇒ nat where
  last-index xs x =
 (let i = index (rev xs) x; n = size xs
```

in if i = n then i else n − (i+1))
