

Stratified Datalog and Program Analysis

Anders Schlichtkrull, René Rydhof Hansen, Flemming Nielson

Abstract

In this entry we formalize stratified Datalog, the first such formalization in Isabelle to the best of our knowledge. Next we formally establish the existence of least solutions for any stratified Datalog program, essential for reasoning about negations in clauses. Lastly we illustrate the usefulness of our Datalog formalization by further formalizing the general Bit-Vector Framework and formalize and prove correct five analyses in this framework namely liveness, reaching definitions, available expressions, very busy expressions and reachability. Many of our definitions follow Nielson and Nielson’s textbook [NN20]. The formalization is described in our SAC 2024 paper [SHN24].

1 Introduction

In the following we develop the first, to the best of our knowledge, Isabelle formalization of Datalog in general and stratified Datalog in particular. We use the formalization to prove the existence of least solutions (to Datalog programs) with respect to a simple ordering on predicate valuations. The ordering is from Nielson and Nielson’s textbook [NNH99], and appears also in a paper by Przymusiński [Prz88] in a different formulation. We prove the two formulations equivalent. Furthermore, we apply our formalization to also formalize so-called *bit-vector analyses* [NNH99] as Datalog programs covering all the usual variants [NN20]: forward may analyses, backward may analyses, forward must analyses, and backward must analyses. The analyses are proved to correctly summarize the paths in the program, and we additionally show that each variant of our Bit-Vector Framework has an instance by formalizing four classic analyses: reaching definitions, live variables, available expressions, and very busy expressions [NNH99]. We use the labeled transition systems formalization by Schlichtkrull et al. [SSST23, SSST22] to represent program graphs.

A Rocq formalization of stratified Datalog, based on the thesis by Dumbrava [Dum16], has been developed by Benzaken et al. [BCD17], giving a comprehensive formalization focusing on correctness of evaluation strategies for (stratified) Datalog programs.

Non-stratified Datalog has been independently formalized in Rocq for use as a stepping stone for formalizing further logics (Binder, Horn clauses, BCiC) used to model and reason about authentication [Whi06] and a subset called Regular Datalog has also been formalized in Rocq [BDA18]. Rocq has also been used to formalize various semantics for Prolog (with corresponding proofs of equivalence), with the goal of proving correctness of static analyses of Prolog programs [KKB13]. Non-stratified Datalog has also been formalized in Lean with the goal of certifying results from Datalog reasoners [TGMK25].

Formalizations of analysis frameworks and the underlying theory have mainly focused on the *abstract interpretation* [CC77] approach to static analysis and primarily using Rocq, with impressive results [CP10, JLB⁺15]. Additionally an Isabelle formalization of abstract interpretation of a small imperative language occurs in the “fully mechanized” semantics textbook of Nipkow [NK14, Nip12].

Concrete program analyses have been formalized and proven correct in Isabelle, as witnessed in the Archive of Formal Proofs¹, including slicing, control flow analysis, conflict analysis, call arity analysis etc. [LMO07, Was08, Bre16, Was09, Bre10, LM08, Imm11, Bre15, Jia21, WL08, WLS09]. These do not use Datalog.

theory Reaching_Definitions imports Bit_Vector_Framework begin
```

— We encode the Reaching Definitions analysis into Datalog. First we define the analysis, then we encode the analysis directly into Datalog and prove the encoding correct. Hereafter we encode it into Datalog again, but this time using our Bit-Vector Framework locale. We also prove this encoding correct. This latter encoding is described in our SAC 2024 paper.
